Q: "Light travels in straight lines. Is it right or wrong?"

Adjust ⚡ — *Negative* / *False* — **Value-Assent Axis** — *Positive* / *True*

A: It is **generally wrong** to say that light always travels in straight lines. **Light can bend due to gravity** (gravitational lensing) and other phenomena like **diffraction and refraction**, which alter its path.

A: It is **generally correct** to say that light travels in straight lines, according to the **principle of rectilinear propagation of light**. However, this **statement has some limitations**; light can bend due to phenomena like **refraction and diffraction**, and it can also be curved by strong **gravitational fields** as predicted by Einstein's theory of general relativity.

A: It is **correct** that light travels in straight lines, known as **rectilinear propagation**. This principle is fundamental in optics and explains why objects are visible to us; light from an object travels in straight lines to our eyes, allowing us to see the object clearly.
